Hello everyone, my name is [NAME], this is [NAME], and this is [NAME], and this is our program, FrogBlog. FrogBlog is a blogging site with simplicity in mind, allowing for users to write and share blog posts, as well as their profiles to friends so they can follow or reply to each other. No bloat, no algorithm, no unnecessary add-ons, just your thoughts and your friends.

We made this to stretch our legs and try to work on something as a team in preparation for our future careers. We chose a blog site, as we figured it would test all facets of our abilities. For example, in the front end it will test our UI and UX design capabilities, our abilities to implement it with modern tools like React, and to style it correctly with CSS and HTML through Vite. In the backend, we wanted to try out new, emerging technologies like Better Auth, as well as industry standards like MongoDB, Express.JS, and Typescript. For our development environment we chose Visual Studio Code with the node package manager npm, ESLint for linting, and Github for our version control.

When it comes to the functionality the first thing we did was lay out the basics of what we wanted the website to do. The first two features you'll be looking at are registration and logging in. Unless we want to make the mistake of letting users on the site remain anonymous, we need to have a secure and working authentication system that persists when you open a new tab. This is where the aforementioned BetterAuth comes in, as it handles all of that in one package with a neat little bow on top. After that, we handled posting and profiles, so people can upload their thoughts and share them around, as well as some simple information like a bio and their birthday. Here's a Live Demo of everything so far in action.

Over the course of writing the software, we ran into a few challenges with getting MongoDB set up and working, but once we figured it out it was pretty smooth sailing from then on, with only a few internal endpoint issues and some merge conflicts here and there. In the future we wish to allow people to edit their posts after they have already uploaded them, reply to posts, in which the functionality is in place it just doesn't work on the front-end yet, like posts, and more.

When it comes to the internal structure of the program, it’s fairly simple. We have a front-end run on the client that queries our middle-man endpoints, requesting only the necessary information for an added layer of protection from the database, and then all the way in the back we have the database which stores all the user and post information.
